## 3-Practice

I - To determine the torsion constant, certain conditions are established to facilitate the measurement and calculation of (C).
$\theta=180^{\circ}$, which can be determined when the indicator LED of the optical barrier lights up. F is directly measured using the dynamometer, and $\varphi=90^{\circ}$.

Consider a steel rod with a mass $\mathrm{m}=132.2 \mathrm{~g}$ and a length $\mathrm{l}=60 \mathrm{~cm}$. The point of force application is adjusted until it balances with the restoring force."

1- Complete the following table:

| $\mathrm{r}(\mathrm{cm})$ | 17 | 19 | 21 | 23 | 25 | 27 | 29 |
| :---: | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{~F}(\mathrm{~N})$ |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |
| $\bar{F}(\mathrm{~N})$ |  |  |  |  |  |  |  |
| $\overline{\bar{F}} \cdot r$ |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |

2- Calculate the average value of the torsion constant $(\overline{\mathrm{C}})$
3- Calculate the average absolute error $(\overline{\Delta C})$
4- Calculate the relative and absolute uncertainty $(\Delta C, \Delta C / C)$
5- Provide the value of $(\mathrm{C})$ in the form $(C=\bar{C} \mp \Delta C)$.
II-
a- Take the rod alone, adjust it so that the axis of rotation passes through its center of mass.
Measureitsperiod five times.

| Order of <br> measurement | 1 | 2 | 3 | 4 | 5 |
| :---: | :--- | :--- | :--- | :--- | :--- |
| $T / 2(s)$ |  |  |  |  |  |

1- Record the result in the table.
2- Provide the value of $(T)$ in the form $(T=\bar{T} \mp \Delta T)$
3- Calculate $\left(\mathrm{I}_{0}\right)$ with respect to an axis passing through the center of mass of the rod
4- Compare the measured value of $\left(\mathrm{I}_{0}\right)$ with the calculated one. Comment.
$\qquad$
$\qquad$
b- Take the rod alone, measure the oscillation period by sliding the rod in steps of ( 4 cm ). Repeat each measurement twice.

## Torsion pendulum

1- Complete the following table.

| $\mathrm{r}(\mathrm{cm})$ | 4 | 8 | 12 | 16 | 20 |
| :---: | :--- | :--- | :--- | :--- | :--- |
| $T / 2(s)$ |  |  |  |  |  |
|  |  |  |  |  |  |
| $\bar{T}(s)$ |  |  |  |  |  |
| $I=C . \bar{T} / 4 \pi^{2}$ |  |  |  |  |  |
| $\left(I-I_{0}\right) / r^{2}$ |  |  |  |  |  |

2- What do you observe about the value of the expression $\left(I-I_{0}\right) / r^{2}$ ? Whatdoesitrepresent?
c- Take a solid sphere, mount it on the rotation axis, and measure its period (take 5measurements).

1- Calculate the average period: $\bar{T}=$
2- Calculate its moment of inertia: $I_{s / 0}=$
3- Compare this value with the one calculated in the theoretical preparation (part 4).
Comment on the results
d-Repeat the same procedure with a solid cylinder.
4- Calculate the average period: $\bar{T}=$
5- Calculate its moment of inertia: $I_{s / 0}=$
6- Compare this value with the one calculated in the theoretical preparation (part 5). Comment on the results

## 4-Conclusion

Torsion pendulum
